**TRYPTOPHANYL-tRNA SYNTHETASE DERIVED POLYPEPTIDES
USEFUL FOR THE REGULATION OF ANGIOGENESIS**

PRIORITY CLAIM

5 This application claims priority to United States Provisional
Application for Patent Serial No. 60/270,951 filed February 23, 2001.

GOVERNMENTAL RIGHTS

 This invention was made with governmental support from the
United States Government, National Institutes of Health, Grant GM23562; the
10 United States Government has certain rights in the invention.

FIELD OF THE INVENTION

 The invention relates to compositions comprising truncated tRNA
synthetase polypeptides, as well as nucleic acids encoding such truncated tRNA
synthetase polypeptides. Methods of making and using such compositions are
15 also disclosed.

BACKGROUND OF THE INVENTION

 Aminoacyl-tRNA synthetases, which catalyze the aminoacylation
of tRNA molecules, are ancient proteins that are essential for decoding genetic
information during the process of translation. In higher eukaryotes, nine
20 aminoacyl-tRNA synthetases associate with at least three other polypeptides to
form a supramolecular multienzyme complex (Mirande *et al.*, *Eur. J. Biochem.*
147:281-89 (1985)). Each of the eukaryotic tRNA synthetases consists of a core
enzyme, which is closely related to the prokaryotic counterpart of the tRNA
synthetase, and an additional domain that is appended to the amino-terminal or
25 carboxyl-terminal end of the core enzyme (Mirande, *Prog. Nucleic Acid Res.*
Mol. Biol. 40:95-142 (1991)).

 In most cases, the appended domains appear to contribute to the
assembly of the multienzyme complex. However, the presence of an extra
domain is not strictly correlated with the association of a synthetase into the
30 multienzyme complex.

 Mammalian TrpRS molecules have an amino-terminal appended
domain. In normal human cells, two forms of TrpRS can be detected: a major

form consisting of the full-length molecule (amino acid residues 1-471 of SEQ ID NO:1) and a minor truncated form ("mini TrpRS"; amino acid residues 1-424 of SEQ ID NO:3). The minor form is generated by the deletion of the amino-terminal domain through alternative splicing of the pre-mRNA (Tolstrup *et al.*, *J. Biol. Chem.* 270:397-403 (1995)). The amino-terminus of mini TrpRS has been determined to be the "met" residue at position 48 of the full-length TrpRS molecule (*id.*). Alternatively, truncated TrpRS can be generated by proteolysis (Lemaire *et al.*, *Eur. J. Biochem.* 51:237-52 (1975)). For example, bovine TrpRS is highly expressed in the pancreas and is secreted into the pancreatic juice (Kisselev, *Biochimie* 75:1027-39 (1993)), thus resulting in the production of a truncated TrpRS molecule. These results suggest that truncated TrpRS can have a function other than the aminoacylation of tRNA (*id.*)

Angiogenesis, or the proliferation of new capillaries from pre-existing blood vessels, is a fundamental process necessary for embryonic development, subsequent growth, and tissue repair. Angiogenesis is a prerequisite for the development and differentiation of the vascular tree, as well as for a wide variety of fundamental physiological processes including embryogenesis, somatic growth, tissue and organ repair and regeneration, cyclical growth of the corpus luteum and endometrium, and development and differentiation of the nervous system. In the female reproductive system, angiogenesis occurs in the follicle during its development, in the corpus luteum following ovulation and in the placenta to establish and maintain pregnancy. Angiogenesis additionally occurs as part of the body's repair processes, e.g. in the healing of wounds and fractures. Angiogenesis is also a factor in tumor growth, since a tumor must continuously stimulate growth of new capillary blood vessels in order to grow. Angiogenesis is an essential part of the growth of human solid cancer, and abnormal angiogenesis is associated with other diseases such as rheumatoid arthritis, psoriasis, and diabetic retinopathy (Folkman, J. and Klagsbrun, M., *Science* 235:442-447 (1987)).

Several factors are involved in angiogenesis. Both acidic and basic fibroblast growth factor molecules that are mitogens for endothelial cells and other cell types. Angiotropin and angiogenin can induce angiogenesis, although

their functions are unclear (Folkman, J., *Cancer Medicine*, pp. 153-170, Lea and Febiger Press (1993)). A highly selective mitogen for vascular endothelial cells is vascular endothelial growth factor or VEGF (Ferrara, N., *et al.*, *Endocr. Rev.* 13:19-32, (1992)).

5 The vast majority of diseases that cause catastrophic loss of vision do so as a result of ocular neovascularization; age related macular degeneration (ARMD) affects 12-15 million American over the age of 65 and causes visual loss in 10-15% of them as a direct effect of choroidal (sub-retinal) neovascularization. The leading cause of visual loss for Americans under the age of 65 is diabetes; 16 million individuals in the United States are diabetic and 40,000 per year suffer from ocular complications of the disease, often a result of retinal neovascularization. While laser photocoagulation has been effective in preventing severe visual loss in subgroups of high risk diabetic patients, the overall 10-year incidence of retinopathy remains substantially unchanged. For patients with choroidal neovascularization due to ARMD or inflammatory eye disease such as ocular histoplasmosis, photocoagulation, with few exceptions, is ineffective in preventing visual loss. While recently developed, non-destructive photodynamic therapies hold promise for temporarily reducing individual loss in patients with previously untreatable choroidal neovascularization, only 61.4% of patients treated every 3-4 months had improved or stabilized vision compared to 45.9% of the placebo-treated group.

25 In the normal adult, angiogenesis is tightly regulated, and is limited to wound healing, pregnancy and uterine cycling. Angiogenesis is turned on by specific angiogenic molecules such as basic and acidic fibroblast growth factor (FGF), vascular endothelial growth factor (VEGF), angiogenin, transforming growth factor (TGF), tumor necrosis factor- α (TNF- α) and platelet derived growth factor (PDGF). Angiogenesis can be suppressed by inhibitory molecules such as interferon- α , thrombospondin-1, angiostatin and endostatin. It is the balance of these naturally occurring stimulators and inhibitors that controls the normally quiescent capillary vasculature. When this balance is upset, as in certain disease states, capillary endothelial cells are induced to proliferate, migrate and ultimately differentiate.

Angiogenesis plays a central role in a variety of disease including cancer and ocular neovascularization. Sustained growth and metastasis of a variety of tumors has also been shown to be dependent on the growth of new host blood vessels into the tumor in response to tumor derived angiogenic factors.

5 Proliferation of new blood vessels in response to a variety of stimuli occurs as the dominant finding in the majority of eye disease and that blind including proliferative diabetic retinopathy (PDR), ARMD, rubeotic glaucoma, interstitial keratitis and retinopathy of prematurity. In these diseases, tissue damage can stimulate release of angiogenic factors resulting in capillary proliferation. VEGF
10 plays a dominant role in iris neovascularization and neovascular retinopathies. While reports clearly show a correlation between intraocular VEGF levels and ischemic retinopathic ocular neovascularization, FGF likely plays a role. Basic and acidic FGF are known to be present in the normal adult retina, even though detectable levels are not consistently correlated with neovascularization. This can
15 be largely due to the fact that FGF binds very tightly to charged components of the extracellular matrix and can not be readily available in a freely diffusible form that would be detected by standard assays of intraocular fluids.

A final common pathway in the angiogenic response involves integrin-mediated information exchange between a proliferating vascular
20 endothelial cell and the extracellular matrix. This class of adhesion receptors, called integrins, are expressed as heterodimers having an α and β subunit on all cells. One such integrin, $\alpha_v\beta_3$, is the most promiscuous member of this family and allows endothelial cells to interact with a wide variety of extracellular matrix components. Peptide and antibody antagonists of this integrin inhibit
25 angiogenesis by selectively inducing apoptosis of the proliferating vascular endothelial cells. Two cytokine-dependent pathways of angiogenesis exist and can be defined by their dependency on distinct vascular cell integrins, $\alpha_v\beta_3$ and $\alpha_v\beta_5$. Specifically, basic FGF- and VEGF-induced angiogenesis depend on integrin $\alpha_v\beta_3$ and $\alpha_v\beta_5$, respectively, since antibody antagonists of each integrin
30 selectively block one of these angiogenic pathways in the rabbit corneal and chick chorioallantoic membrane (CAM) models. Peptide antagonists that block all α_v integrins inhibit FGF- and VEGF-stimulated angiogenesis. While normal human

ocular blood vessels do not display either integrin, $\alpha_v\beta_3$ and $\alpha_v\beta_5$ integrins are selectively displayed on blood vessels in tissues from patients with active neovascular eye disease. While only $\alpha_v\beta_3$ was consistently observed in tissue from patients with ARMD, $\alpha_v\beta_3$ and $\alpha_v\beta_5$ both were present in tissues from patients with PDR. Systemically administered peptide antagonists of itegrins blocked new blood vessel formation in a mouse model of retinal vasculogenesis

Hence, anti-angiogenic agents have a role in treating retinal degeneration to prevent the damaging effects of these trophic and growth factors. Angiogenic agents, also have role in promoting desirable vascularization to retard retinal degeneration by enhancing blood flow to cells.

SUMMARY OF THE INVENTION

Tryptophanyl-tRNA synthetase derived polypeptides, shorter than the ones that occur in Nature, have chemokine activity and are useful for research, diagnostic, prognostic and therapeutic applications. In one embodiment, these tRNA synthetase derived polypeptides are useful for regulating vascular endothelial cell function, and in particular, for inhibiting angiogenesis, especially ocular neovascularization.

These truncated tryptophanyl-tRNA synthetase derived polypeptides have an amino-terminal truncation, but can include a Rossmann fold nucleotide binding domain. These polypeptides are capable of regulating vascular endothelial cell function.

A preferred truncated tryptophanyl-tRNA synthetase derived polypeptide includes a polypeptide consisting essentially of amino acid residues 94-471 of SEQ ID NO:1 and angiogenesis-inhibiting fragments thereof, especially those bracketed by the signature sequences shown in SEQ ID NO:10 and SEQ ID NO:11, or that include at least one of these signature sequences. In one preferred embodiment, the truncated tRNA synthetase polypeptide is mammalian, and more preferably, human.

In another embodiment, the invention comprises an isolated polynucleotide having a nucleotide sequence at least 95% identical to the sequence of a polynucleotide selected from the group consisting of a polynucleotide of SEQ ID NO:6, a polynucleotide which is hybridizable to a

polynucleotide of SEQ ID NO:6; a polynucleotide encoding the polypeptide of
SEQ ID NO:7; a polynucleotide encoding the polypeptide of SEQ ID NO:12, a
polynucleotide encoding a polypeptide epitope of SEQ ID NO:7; and a
polynucleotide that is hybridizable to a polynucleotide encoding a polypeptide
epitope of SEQ ID NO:7. The present invention also includes a recombinant
expression vector comprising an isolated nucleic acid molecule that encodes any
of the aforementioned tryptophanyl-tRNA synthetase derived polypeptides.
Another embodiment is a host cell comprising such a recombinant expression
vector.

The invention additionally provides composition and dosage forms
that include the truncated tryptophanyl-tRNA synthetase derived polypeptides
together with a pharmaceutically suitable excipient. Such compositions are
suitable for intraocular, e.g., intravitreal, sub-retinal or the like, as well as for
systemic administration, e.g., transdermal, transmucosal, enteral or parenteral
administration.

In another embodiment, the invention provides a method of
treating neovascular eye diseases such as age-related macular degeneration,
ocular complications of diabetes, rubeotic glaucoma, retinopathy of prematurity,
keratitis, ischemic, retinopathy (e.g., sickle cell), pathological myopic, ocular
histoplasmosis, pterygia, punitate inner choroidopathy, and the like, by
administering an angiogenesis inhibiting amount of the polypeptide together with
an appropriate, physiologically compatible excipient or carrier.

BRIEF DESCRIPTION OF THE DRAWINGS

In the drawings,

FIGURE 1 shows the amino acid residue sequence of
tryptophanyl-t-RNA synthetase polypeptide (SEQ ID NO:1) with included
signature sequences (SEQ ID NO:10 & SEQ ID NO:11), shown in a box,
encompassed also within the truncated form (amino acid residue sequences 94-
471 of SEQ ID NO:1);

FIGURE 2 is a photomicrograph that illustrates retinal vascular
development in a mouse model;

FIGURE 3 is a graphical representation of data reported in Example 3, below;

FIGURE 4 is a graphical representation of data reported in Example 4, below; and

5 FIGURE 5 is a photomicrograph that illustrates the binding localization of a fragment of TrpRS (T2) in the retina in a mouse model.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Definitions

10 "Truncated tRNA synthetase polypeptides" means polypeptides that are shorter than the corresponding full length tRNA synthetase.

 "TrpRS" means tryptophanyl-tRNA synthetase.

 "Cell culture" encompasses both the culture medium and the cultured cells.

15 The phrase "isolating a polypeptide from the cell culture" encompasses isolating a soluble or secreted polypeptide from the culture medium as well as isolating an integral membrane protein from the cultured cells.

20 "Cell extract" includes culture media, especially spent culture media from which the cells have been removed. A cell extract that contains the DNA or protein of interest should be understood to mean a homogenate preparation or cell-free preparation obtained from cells that express the protein or contain the DNA of interest.

25 "Plasmid" is an autonomous, self-replicating extrachromosomal DNA molecule and is designated by a lower case "p" preceded and/or followed by capital letters and/or numbers. The starting plasmids herein are either commercially available, publicly available on an unrestricted basis, or can be constructed from available plasmids in accord with published procedures. In addition, equivalent plasmids to those described are known in the art and will be apparent to the ordinarily skilled artisan.

30 "Digestion" of DNA refers to catalytic cleavage of the DNA with a restriction enzyme that acts only at certain sequences in the DNA. The various restriction enzymes used herein are commercially available and their reaction conditions, cofactors and other requirements were used as would be known to the

ordinarily skilled artisan. For analytical purposes, typically 1 µg of plasmid or DNA fragment is used with about 2 units of enzyme in about 20 µl of buffer solution. For the purpose of isolating DNA fragments for plasmid construction, typically 5 to 50 µg of DNA are digested with 20 to 250 units of enzyme in a larger volume. Appropriate buffers and substrate amounts for particular restriction enzymes are specified by the manufacturer. Incubation times of about 1 hour at 37 °C. are ordinarily used, but can vary in accordance with the supplier's instructions. After digestion the reaction is electrophoresed directly on a poly-acrylamide gel to isolate the desired fragment. The nucleotides present in various DNA and RNA fragments are designated herein by the standard single letter designations (A, T, C, G, U) used in the art.

"Polynucleotide" embodying the present invention can be in the form of RNA or in the form of DNA, which DNA includes cDNA, genomic DNA, and synthetic DNA. The DNA can be double-stranded or single-stranded, and if single stranded can be the coding strand or non-coding (anti-sense) strand. The coding sequence which encodes the mature polypeptide can be identical to the coding sequence shown in SEQ ID NO:6 or can be a different coding sequence which coding sequence, as a result of the redundancy or degeneracy of the genetic code, encodes the same, mature polypeptide sequence shown in SEQ ID NO:7.

The term "Polynucleotide encoding a polypeptide" encompasses a polynucleotide which includes only coding sequence for the polypeptide as well as a polynucleotide which includes additional coding and/or non-coding sequence.

"Oligonucleotides" refers to either a single stranded polynucleotide or two complementary polynucleotide strands which can be chemically synthesized. Such synthetic oligonucleotides have no 5' phosphate and thus will not ligate to another oligonucleotide without adding a phosphate with an ATP in the presence of a kinase. A synthetic oligonucleotide will ligate to a fragment that has not been dephosphorylated.

"Amino acid residue" refers to an amino acid which is part of a polypeptide. The amino acid residues described herein are preferably in the L" isomeric form. However, residues in the D" isomeric form can be substituted for

any L-amino acid residue, as long as the desired functional property is retained by the polypeptide. NH₂ refers to the free amino group present at the amino terminus of a polypeptide. COOH refers to the free carboxy group present at the carboxyl terminus of a polypeptide. In keeping with standard polypeptide nomenclature described in *J. Biol. Chem.*, 243:3552-59 (1969) and adopted at 37 C.F.R. § § 1.821 - 1.822, abbreviations for amino acid residues are shown in the following Table:

Table 1
Table of Correspondence

10

SYMBOL

15

20

25

30

35

1-Letter	3-Letter	AMINO ACID
Y	Tyr	tyrosine
G	Gly	glycine
F	Phe	phenylalanine
M	Met	methionine
A	Ala	alanine
S	Ser	serine
I	Ile	isoleucine
L	Leu	leucine
T	Thr	threonine
V	Val	valine
P	Pro	proline
K	Lys	lysine
H	His	histidine
Q	Gln	glutamine
E	Glu	glutamic acid
Z	Glx	Glu and/or Gln
W	Trp	tryptophan
R	Arg	arginine
D	Asp	aspartic acid
N	Asn	asparagine
B	Asx	Asn and/or Asp
C	Cys	cysteine
X	Xaa	Unknown or other

All amino acid residue sequences represented herein by formulae have a left to right orientation in the conventional direction of amino-terminus to carboxyl-terminus. In addition, the phrase "amino acid residue" is broadly defined to include the amino acids listed in Table 1 as well as modified and unusual amino acids, such as those referred to in 37 C.F.R. § § 1.821-1.822, and incorporated herein by reference. A dash at the beginning or end of an amino acid residue sequence indicates a peptide bond to a further sequence of one or more amino acid residues or to an amino-terminal group such as NH₂ or to a carboxyl-terminal group such as COOH.

In a peptide or protein, suitable conservative substitutions of amino acids are known to those of skill in this art and can be made generally without altering the biological activity of the resulting molecule. Those of skill in this art recognize that, in general, single amino acid substitutions in non-essential regions of a polypeptide do not substantially alter biological activity (see, *e.g.*, Watson *et al. Molecular Biology of the Gene*, 4th Edition, 1987, The Benjamin/Cummings Pub. Co., p.224).

Such substitutions are preferably made in accordance with those set forth in TABLE 2 as follows:

TABLE 2

Original residue	Conservative substitution
Ala (A)	Gly; Ser
Arg (R)	Lys
Asn (N)	Gln; His
Cys (C)	Ser
Gln (Q)	Asn
Glu (E)	Asp
Gly (G)	Ala; Pro
His (H)	Asn; Gln
Ile (I)	Leu; Val
Leu (L)	Ile; Val
Lys (K)	Arg; Gln; Glu
Met (M)	Leu; Tyr; Ile
Phe (F)	Met; Leu; Tyr
Ser (S)	Thr
Thr (T)	Ser

Original residue	Conservative substitution
Trp (W)	Tyr
Tyr (Y)	Trp; Phe
Val (V)	Ile; Leu

5 Other substitutions are also permissible and can be determined empirically or in accord with known conservative substitutions.

"Complementing plasmid" describes plasmid vectors that deliver nucleic acids into a packaging cell line for stable integration into a chromosome in the cellular genome.

10 "Delivery plasmid" is a plasmid vector that carries or delivers nucleic acids encoding a therapeutic gene or gene that encodes a therapeutic product or a precursor thereof or a regulatory gene or other factor that results in a therapeutic effect when delivered *in vivo* in or into a cell line, such as, but not limited to a packaging cell line, to propagate therapeutic viral vectors.

15 A variety of vectors is described herein. For example, one vector is used to deliver particular nucleic acid molecules into a packaging cell line for stable integration into a chromosome. These types of vectors are generally identified herein as complementing plasmids. A further type of vector described herein carries or delivers nucleic acid molecules in or into a cell line (*e.g.*, a packaging cell line) for the purpose of propagating therapeutic viral vectors; hence, these vectors are generally referred to herein as delivery plasmids. A third "type" of vector described herein is used to carry nucleic acid molecules encoding therapeutic proteins or polypeptides or regulatory proteins or are regulatory sequences to specific cells or cell types in a subject in need of treatment; these vectors are generally identified herein as therapeutic viral vectors or recombinant adenoviral vectors or viral Ad-derived vectors and are in the form of a virus particle encapsulating a viral nucleic acid containing an expression cassette for expressing the therapeutic gene.

25 "DNA or nucleic acid homolog" refers to a nucleic acid that includes a preselected conserved nucleotide sequence, such as a sequence encoding a therapeutic polypeptide. By the term "substantially homologous" is meant having at least 80%, preferably at least 90%, most preferably at least 95%

homology therewith or a less percentage of homology or identity and conserved biological activity or function.

The terms "homology" and "identity" are often used interchangeably. In this regard; degree of homology or identity can be
5 determined, for example, by comparing sequence information using a GAP computer program. The GAP program utilizes the alignment method of Needleman and Wunsch, *J. Mol. Biol.* 48:443 (1970), as revised by Smith and Waterman, *Adv. Appl. Math.* 2:482 (1981). Briefly, the GAP program defines similarity as the number of aligned symbols (i.e., nucleotides or amino acids)
10 which are similar, divided by the total number of symbols in the shorter of the two sequences. The preferred default parameters for the GAP program can include: (1) a unary comparison matrix (containing a value of 1 for identities and 0 for non-identities) and the weighted comparison matrix of Gribskov and Burgess, *Nucl. Acids Res.* 14:6745 (1986), as described by Schwartz and
15 Dayhoff, eds., *Atlas of Protein Sequence and Structure*, National Biomedical Research Foundation, pp. 353-358 (1979); (2) a penalty of 3.0 for each gap and an additional 0.10 penalty for each symbol in each gap; and (3) no penalty for end gaps. Whether any two nucleic acid molecules have nucleotide sequences that are at least 80%, 85%, 90%, 95%, 96%, 97%, 98% or 99% "identical" can
20 be determined using known computer algorithms such as the "FAST A" program, using for example, the default parameters as in Pearson and Lipman, *Proc. Natl. Acad. Sci. USA* 85:2444 (1988). Alternatively the BLAST function of the National Center for Biotechnology Information database can be used to determine identity. In general, sequences are aligned so that the highest order match is
25 obtained. "Identity" *per se* has an art-recognized meaning and can be calculated using published techniques. (See, e.g.: *Computational Molecular Biology*, Lesk, A.M., ed., Oxford University Press, New York, (1988); Smith, D.W., ed., *Biocomputing: Informatics and Genome Projects*, Academic Press, New York, (1993); Griffin, A.M., and Griffin, H.G., eds., *Computer Analysis of Sequence*
30 *Data, Part I*, Humana Press, New Jersey, (1994); von Heinje, G., *Sequence Analysis in Molecular Biology*, Academic Press, (1987); and Gribskov, M. and Devereux, J., eds., *Sequence Analysis Primer*, M Stockton Press, New York,

(1991)). While there exist a number of methods to measure identity between two polynucleotide or polypeptide sequences, the term "identity" is well known to skilled artisans (Carillo, H. & Lipton, D., *SIAM J. Applied Math.* 48:1073 (1988)). Methods commonly employed to determine identity or similarity
5 between two sequences include, but are not limited to, those disclosed in Martin J. Bishop, ed., *Guide to Huge Computers*, Academic Press, San Diego, (1994), and Carillo, H. & Lipton, D., *SIAM J. Applied Math.* 48:1073 (1988). Methods to determine identity and similarity are codified in computer programs. Preferred computer program methods to determine identity and similarity between two
10 sequences include, but are not limited to, GCG program package (Devereux, J., *et al.*, *Nucleic Acids Research* 12(I):387 (1984)), BLASTP, BLASTN, FASTA (Atschul, S.F., *et al.*, *J. Molec. Biol.* 215:403 (1990)).

The term "identity" represents a comparison between a test and a reference polypeptide or polynucleotide. For example, a test polypeptide can be
15 defined as any polypeptide that is 90% or more identical to a reference polypeptide. As used herein, the term at least "90% identical to" refers to percent identities from 90 to 99.99 relative to the reference polypeptides. Identity at a level of 90% or more is indicative of the fact that, assuming for exemplification purposes a test and reference polynucleotide length of 100 amino
20 acids are compared. No more than 10% (i.e., 10 out of 100) amino acids in the test polypeptide differs from that of the reference polypeptides. Similar comparisons can be made between a test and reference polynucleotides. Such differences can be represented as point mutations randomly distributed over the entire length of an amino acid sequence or they can be clustered in one or more
25 locations of varying length up to the maximum allowable, e.g. 10/100 amino acid difference (approximately 90% identity). Differences are defined as nucleic acid or amino acid substitutions, or deletions.

The terms "gene therapy" and "genetic therapy" refer to the transfer of heterologous DNA to the certain cells, target cells, of a mammal,
30 particularly a human, with a disorder or conditions for which such therapy is sought. The DNA is introduced into the selected target cells in a manner such that the heterologous DNA is expressed and a therapeutic product encoded

thereby is produced. Alternatively, the heterologous DNA can in some manner mediate expression of DNA that encodes the therapeutic product, it can encode a product, such as a peptide or RNA that in some manner mediates, directly or indirectly, expression of a therapeutic product. Genetic therapy can also be used to nucleic acid encoding a gene product replace a defective gene or supplement a gene product produced by the mammal or the cell in which it is introduced. The introduced nucleic acid can encode a therapeutic compound, such as a growth factor inhibitor thereof, or a tumor necrosis factor or inhibitor thereof, such as a receptor therefor, that is not normally produced in the mammalian host or that is not produced in therapeutically effective amounts or at a therapeutically useful time. The heterologous DNA encoding the therapeutic product can be modified prior to introduction into the cells of the afflicted host in order to enhance or otherwise alter the product or expression thereof.

"Heterologous DNA" is DNA that encodes RNA and proteins that are not normally produced *in vivo* by the cell in which it is expressed or that mediates or encodes mediators that alter expression of endogenous DNA by affecting transcription, translation, or other regulatable biochemical processes. Heterologous DNA can also be referred to as foreign DNA. Any DNA that one of skill in the art would recognize or consider as heterologous or foreign to the cell in which is expressed is herein encompassed by heterologous DNA. Examples of heterologous DNA include, but are not limited to, DNA that encodes traceable marker proteins, such as a protein that confers drug resistance, DNA that encodes therapeutically effective substances, such as anti-cancer agents, enzymes and hormones, and DNA that encodes other types of proteins, such as antibodies. Antibodies that are encoded by heterologous DNA can be secreted or expressed on the surface of the cell in which the heterologous DNA has been introduced. Hence, "heterologous DNA" or "foreign DNA", refers to a DNA molecule not present in the exact orientation and position as the counterpart DNA molecule found in the corresponding wild-type adenovirus. It can also refer to a DNA molecule from another organism or species (*i.e.*, exogenous) or from another Ad serotype.

"Therapeutically effective DNA product" is a product that is encoded by heterologous DNA so that, upon introduction of the DNA into a host, a product is expressed that effectively ameliorates or eliminates the symptoms, manifestations of an inherited or acquired disease or that cures said disease.

5 Typically, DNA encoding the desired heterologous DNA is cloned into a plasmid vector and introduced by routine methods, such as calcium-phosphate mediated DNA uptake or microinjection, into producer cells, such as packaging cells. After amplification in producer cells, the vectors that contain the heterologous DNA are introduced into selected target cells.

10 "Expression or delivery vector" refers to any plasmid or virus into which a foreign or heterologous DNA can be inserted for expression in a suitable host cell — *i.e.*, the protein or polypeptide encoded by the DNA is synthesized in the host cell's system. Vectors capable of directing the expression of DNA segments (genes) encoding one or more proteins are referred to herein as
15 "expression vectors." Also included are vectors that allow cloning of cDNA (complementary DNA) from mRNAs produced using reverse transcriptase.

"Gene" is a nucleic acid molecule whose nucleotide sequence encodes RNA or polypeptide. A gene can be either RNA or DNA. Genes can include regions preceding and following the coding region (leader and trailer) as
20 as well as intervening sequences (introns) between individual coding segments (exons).

"Isolated" with reference to a nucleic acid molecule, polypeptide, or other biomolecule, means that the nucleic acid or polypeptide has separated from the genetic environment from which the polypeptide or nucleic acid were
25 obtained. It can also mean altered from the natural state. For example, a polynucleotide or a polypeptide naturally present in a living animal is not "isolated," but the same polynucleotide or polypeptide separated from the coexisting materials of its natural state is "isolated", as the term is employed herein. Thus, a polypeptide or polynucleotide produced and/or contained within
30 a recombinant host cell is considered isolated. Also intended as an "isolated polypeptide" or an "isolated polynucleotide" are polypeptides or polynucleotides that have been purified, partially or substantially, from a recombinant host cell or

from a native source. For example, a recombinantly produced version of a compound can be substantially purified by the one-step method described in Smith and Johnson, *Gene* 67:31-40 (1988). The terms "isolated" and "purified" are sometimes used interchangeably. Such polynucleotide could be part of a vector and/or such polynucleotide or polypeptide could be part of a composition, and still be isolated in that such vector or composition is not part of its natural environment.

By "isolated polynucleotide" is meant that the nucleic acid is free of the coding sequences of those genes that, in the naturally-occurring genome of the organism (if any) immediately flank the gene encoding the nucleic acid of interest. Isolated DNA can be single-stranded or double-stranded, and can be genomic DNA, cDNA, recombinant hybrid DNA, or synthetic DNA. It can be identical to a native DNA sequence, or can differ from such sequence by the deletion, addition, or substitution of one or more nucleotides.

"Isolated" or "purified" as it refers to preparations made from biological cells or hosts means any cell extract containing the indicated DNA or protein including a crude extract of the DNA or protein of interest. For example, in the case of a protein, a purified preparation can be obtained following an individual technique or a series of preparative or biochemical techniques and the DNA or protein of interest can be present at various degrees of purity in these preparations. The procedures can include for example, but are not limited to, ammonium sulfate fractionation, gel filtration, ion exchange chromatography, affinity chromatography, density gradient centrifugation and electrophoresis.

A preparation of DNA or protein that is "substantially pure" or "isolated" means a preparation free from naturally occurring materials with which such DNA or protein is normally associated in nature. "Essentially pure" should be understood to mean a "highly" purified preparation that contains at least 95% of the DNA or protein of interest.

"Packaging cell line" is a cell line that provides a missing gene product or its equivalent.

"Adenovirus viral particle" is the minimal structural or functional unit of a virus. A virus can refer to a single particle, a stock of particles or a viral genome. The adenovirus (Ad) particle is relatively complex and can be resolved into various substructures.

5 "Post-transcription regulatory element (PRE)" is a regulatory element found in viral or cellular messenger RNA that is not spliced, i.e. intronless messages. Examples include, but are not limited to, human hepatitis virus, woodchuck hepatitis virus, the TK gene and mouse histone gene. The PRE can be placed before a polyA sequence and after a heterologous DNA
10 sequence.

"Pseudotyping" describes the production of adenoviral vectors having modified capsid protein or capsid proteins from a different serotype than the serotype of the vector itself. One example, is the production of an adenovirus
15 5 vector particle containing an Ad37 fiber protein. This can be accomplished by producing the adenoviral vector in packaging cell lines expressing different fiber proteins.

"Promoters of interest herein" can be inducible or constitutive. Inducible promoters will initiate transcription only in the presence of an additional molecule; constitutive promoters do not require the presence of any
20 additional molecule to regulate gene expression. a regulatable or inducible promoter can also be described as a promoter where the rate or extent of RNA polymerase binding and initiation is modulated by external stimuli. Such stimuli include, but are not limited to various compounds or compositions, light, heat, stress and chemical energy sources. Inducible, suppressible and repressible
25 promoters are considered regulatable promoters. Preferred promoters herein, are promoters that are selectively expressed in ocular cells, particularly photoreceptor cells.

"Receptor" refers to a biologically active molecule that specifically binds to (or with) other molecules. The term "receptor protein" can be used to
30 more specifically indicate the proteinaceous nature of a specific receptor.

"Recombinant" refers to any progeny formed as the result of genetic engineering. This can also be used to describe a virus formed by recombination of plasmids in a packaging cell.

5 "Transgene" or "therapeutic nucleic acid molecule" includes DNA and RNA molecules encoding an RNA or polypeptide. Such molecules can be "native" or naturally-derived sequences; they can also be "non-native" or "foreign" that are naturally- or recombinantly-derived. The term "transgene," which can be used interchangeably herein with the term "therapeutic nucleic acid molecule," is often used to describe a heterologous or foreign (exogenous) gene
10 that is carried by a viral vector and transduced into a host cell. Therapeutic nucleotide nucleic acid molecules include antisense sequences or nucleotide sequences which can be transcribed into antisense sequences. Therapeutic nucleotide sequences (or transgenes) all include nucleic acid molecules that function to produce a desired effect in the cell or cell nucleus into which said
15 therapeutic sequences are delivered. For example, a therapeutic nucleic acid molecule can include a sequence of nucleotides that encodes a functional protein intended for delivery into a cell which is unable to produce that functional protein.

20 "Vitreous of the eye" refers to a material that fills the chamber behind the lens of the eye (i.e., vitreous humor or vitreous body).

"Promoter region" refers to the portion of DNA of a gene that controls transcription of the DNA to which it is operatively linked. The promoter region includes specific sequences of DNA that are sufficient for RNA polymerase recognition, binding and transcription initiation. This portion of the
25 promoter region is referred to as the promoter. In addition, the promoter region includes sequences that modulate this recognition, binding and transcription initiation activity of the RNA polymerase. These sequences can be *cis* acting or can be responsive to *trans* acting factors. Promoters, depending upon the nature of the regulation, can be constitutive or regulated.

30 "Operatively linked" means that the sequences or segments have been covalently joined into one piece of DNA, whether in single or double stranded form, whereby control sequences on one segment control expression or

replication or other such control of other segments. The two segments are not necessarily contiguous, however.

"Package" refers to a solid matrix or material such as glass, plastic (e.g., polyethylene, polypropylene or polycarbonate), paper, foil and the like capable of holding within fixed limits a polypeptide, polyclonal antibody, or monoclonal antibody of the present invention. Thus, for example, a package can be a glass vial used to contain milligram quantities of a contemplated polypeptide or it can be a microtiter plate well to which microgram quantities of a contemplated polypeptide or antibody have been operatively affixed (i.e., linked) so as to be capable of being immunologically bound by an antibody or antigen, respectively.

"Instructions for use" typically include a tangible expression describing the reagent concentration or at least one assay method parameter, such as the relative amounts of reagent and sample to be admixed, maintenance time periods for reagent/ sample admixtures, temperature, buffer conditions and the like.

"Diagnostic system" in the context of the present invention also includes a label or indicating means capable of signaling the formation of an immunocomplex containing a polypeptide or antibody molecule of the present invention.

"Complex" as used herein refers to the product of a specific binding reaction such as an antibody-antigen or receptor-ligand reaction. Exemplary complexes are immunoreaction products.

"Label" and "Indicating means" in their various grammatical forms refer to single atoms and molecules that are either directly or indirectly involved in the production of a detectable signal to indicate the presence of a complex. Any label or indicating means can be linked to or incorporated in an expressed protein, polypeptide, or antibody molecule that is part of an antibody or monoclonal antibody composition of the present invention or used separately, and those atoms or molecules can be used alone or in conjunction with additional reagents. Such labels are themselves well-known in clinical diagnostic chemistry

and constitute a part of this invention only insofar as they are utilized with otherwise novel proteins methods and/or systems.

Discussion

5 The polypeptide shown in FIGURE 1 as amino acid residues 94-471 of SEQ ID NO:1 (e.g., SEQ ID NO:12), as well as that having the amino acid sequence of SEQ ID NO:7, or the polypeptide encoded by the cDNA of SEQ ID NO:6, constitute parts of the present invention. In addition to variants of the above polypeptides, the present invention also includes variants of polynucleotides. Included polynucleotide variants can be a naturally occurring
10 allelic variant of the polynucleotide or a non-naturally occurring variant of the polynucleotide. Thus, the present invention includes polynucleotides encoding the same polypeptide as shown in SEQ ID NO:7, SEQ ID NO:12, and the polypeptide encoded by the cDNA of SEQ ID NO:6 as well as variants of such polynucleotides which variants encode for an angiogenesis inhibiting fragment, derivative or analog of the polypeptides of SEQ ID NO:7 and SEQ ID NO:12.
15 Such nucleotide variants include deletion variants, substitution variants and addition or insertion variants.

As indicated above, the polynucleotide can have a coding sequence which is a naturally occurring allelic variant of the coding sequence shown in
20 SEQ ID NO:6. As known in the art, an allelic variant is an alternate form of a polynucleotide sequence which have a substitution, deletion or addition of one or more nucleotides, which does not substantially alter the function of the encoded polypeptide.

As used herein, the term T1 refers to both the polypeptide having
25 the amino acid sequence of SEQ ID NO: 13 and to the His₆-tagged polypeptide having the amino acid sequence of SEQ ID NO: 5. The term T2, as uses herein, refers to both the polypeptide having the amino acid sequence of SEQ ID NO: 12 and to the His₆-tagged polypeptide having the amino acid sequence of SEQ ID NO: 7. The term TrpRS, as uses herein, refers to both the polypeptide having
30 the amino acid sequence of residues 1-471 of SEQ ID NO: 1 and to the His₆-tagged polypeptide having the amino acid sequence of SEQ ID NO: 1.

The present invention also includes polynucleotides wherein the coding sequence for the mature polypeptide can be fused in the same reading frame to a polynucleotide which aids in expression and secretion of a polypeptide from a host cell, for example, a leader sequence which functions as a secretory sequence for controlling transport of a polypeptide from the cell. The polypeptide having a leader sequence is a preprotein and can have the leader sequence cleaved by the host cell to form the mature form of the polypeptide. The polynucleotides can also encode for a proprotein which is the mature protein plus additional 5' amino acid residues. A mature protein having a prosequence is a proprotein and is an inactive form of the protein. Once the prosequence is cleaved an active mature protein remains.

Thus, for example, the polynucleotide of the present invention can encode for a mature protein, or for a protein having a prosequence or for a protein having both a prosequence and presequence (leader sequence).

The polynucleotides of the present invention can also have the coding sequence fused in frame to a marker sequence which allows for purification of the polypeptide of the present invention. The marker sequence can be a hexa-histidine tag supplied by a pQE-9 vector to provide for purification of the mature polypeptide fused to the marker in the case of a bacterial host, or, for example, the marker sequence can be a hemagglutinin (HA) tag when a mammalian host, e.g. COS-7 cells, is used. The HA tag corresponds to an epitope derived from the influenza hemagglutinin protein (Wilson, I., *et al.*, *Cell*, 37:767 (1984)).

The present invention further relates to polynucleotides which hybridize to the hereinabove-described sequences if there is at least 50% and preferably 70% identity between the sequences. The present invention particularly relates to polynucleotides which hybridize under stringent conditions to the hereinabove-described polynucleotides. As herein used, the term "stringent conditions" means hybridization will occur only if there is at least 95% and preferably at least 97% identity between the sequences. The polynucleotides which hybridize to the hereinabove described polynucleotides in a preferred embodiment encode polypeptides which retain substantially the same biological

function or activity as the mature polypeptide encoded by the cDNA of SEQ ID NO:6.

When referring to the polypeptide of SEQ ID NO:7, SEQ ID NO:12, or to a polypeptide encoded by the polynucleotide of SEQ ID NO:6, the terms "fragment," "derivative" and "analog" mean a polypeptide portion which retains substantially the same angiostatic (i.e., angiogenesis inhibiting) function or activity as such polypeptide. Thus, an "analog" includes a proprotein which can be activated by cleavage of the proprotein portion to produce an angiostatically active mature polypeptide.

The polypeptide of the present invention can be a recombinant polypeptide, a natural polypeptide or a synthetic polypeptide, preferably a recombinant polypeptide.

The angiogenesis inhibiting fragment, derivative or analog of the polypeptide of SEQ ID NO:7, SEQ ID NO:12, or the polypeptide encoded by the polynucleotide of SEQ ID NO:6 can be (i) one in which one or more of the amino acid residues are substituted with a conserved or non-conserved amino acid residue (preferably a conserved amino acid residue) and such substituted amino acid residue can or can not be one encoded by the genetic code, or (ii) one in which one or more of the amino acid residues includes a substituent group, or (iii) one in which the polypeptide is fused with another compound, such as a compound to increase the half-life of the polypeptide (for example, polyethylene glycol), or (iv) one in which the additional amino acids are fused to the polypeptide, such as a leader or secretory sequence or a sequence which is employed for purification of the polypeptide or a proprotein sequence. Such fragments, derivatives and analogs are deemed to be within the scope of those skilled in the art from the teachings herein.

The polypeptides and polynucleotides of the present invention are preferably provided in an isolated form, and preferably are purified to homogeneity.

The present invention also includes vectors which include polynucleotides of the present invention, host cells which are genetically

engineered with vectors of the invention and the production of polypeptides of the invention by recombinant techniques.

Host cells are genetically engineered (transduced or transformed or transfected) with the vectors of this invention which can be, for example, a
5 cloning vector or an expression vector. The vector can be, for example, in the form of a plasmid, a viral particle, a phage, etc. The engineered host cells can be cultured in conventional nutrient media modified as appropriate for activating promoters, selecting transformants or amplifying the tRNA synthetase polypeptide genes. The culture conditions, such as temperature, pH and the like, are those
10 previously used with the host cell selected for expression, and will be apparent to the ordinarily skilled artisan.

The polynucleotides of the present invention can be utilized for producing corresponding polypeptides by recombinant techniques. Thus, for example, the polynucleotide sequence can be included in any one of a variety of
15 expression vehicles, in particular vectors or plasmids for expressing a polypeptide. Such vectors include chromosomal, nonchromosomal and synthetic DNA sequences, e.g., derivatives of SV40; bacterial plasmids; phage DNA; yeast plasmids; vectors derived from combinations of plasmids and phage DNA, viral DNA such as vaccinia, adenovirus, fowl pox virus, and pseudorabies. A
20 preferred vector is pET20b. However, any other plasmid or vector can be used as long as it is replicable and viable in the host.

As described above, the appropriate DNA sequence can be inserted into the vector by a variety of procedures. In general, the DNA sequence is inserted into an appropriate restriction endonuclease sites by procedures known in
25 the art. Such procedures and others are deemed to be within the scope of those skilled in the art.

The DNA sequence in the expression vector is operatively linked to an appropriate expression control sequence(s) (promoter) to direct mRNA synthesis. Representative examples of such promoters include LTR or SV40
30 promoter, the *E. coli* lac or trp promoters, the phage lambda P_L promoter and other promoters known to control expression of genes in prokaryotic or eukaryotic cells or their viruses. The expression vector also contains a ribosome

binding site for translation initiation and a transcription terminator. The vector can also include appropriate sequences for amplifying expression.

5 In addition, the expression vectors preferably contain a gene to provide a phenotypic trait for selection of transformed host cells such as dihydrofolate reductase or neomycin resistance for eukaryotic cell culture, or such as tetracycline or ampicillin resistance in *E. coli*.

10 The vector containing the appropriate DNA sequence as herein above described, as well as an appropriate promoter or control sequence, can be employed to transform an appropriate host to permit the host to express the protein. Representative examples of appropriate hosts include bacterial cells, such as *E. coli*, *Salmonella typhimurium*, *Streptomyces*; fungal cells, such as yeast; insect cells, such as *Drosophila* and Sf9; animal cells such as CHO, COS or Bowes melanoma; plant cells, etc. The selection of an appropriate host is deemed to be within the scope of those skilled in the art from the teachings
15 herein.

More particularly, the present invention also includes recombinant constructs comprising one or more of the sequences as broadly described above. The constructs comprise a vector, such as a plasmid or viral vector, into which a sequence of the invention has been inserted, in a forward or reverse orientation.
20 In a preferred aspect of this embodiment, the construct further comprises regulatory sequences, including, for example, a promoter, operably linked to the sequence. Large numbers of suitable vectors and promoters are known to those of skill in the art, and are commercially available. The following vectors are provided by way of example: Bacterial: pQE70, pQE-9 (Qiagen), pBs, phagescript, PsiX174, pBluescript SK, pBsKS, pNH8a, pNH16a, pNH18a, pNH46a (Stratagene); pTrc99A, pKK223-3, pKK233-3, pDR540, PRIT5 (Pharmacia). Eukaryotic: pWLneo, pSV2cat, pOG44, pXT1, pSG (Stratagene) pSVK3, pBPV, PMSG, pSVL (Pharmacia) and pET20B. In one preferred
25 embodiment, the vector is pET20B. However, any other plasmid or vector can be used as long as they are replicable and viable in the host.
30

Promoter regions can be selected from any desired gene using CAT (chloramphenicol transferase) vectors or other vectors with selectable

markers. Two appropriate vectors are pKK232-8 and pCM7. Particular named bacterial promoters include lacI, lacZ, T3, T7, gpt, lambda P_R, PL and trp. Eukaryotic promoters include CMV immediate early, HSV thymidine kinase, early and late SV40, LTRs from retrovirus, and mouse metallothionein-I.

5 Selection of the appropriate vector and promoter is well within the level of ordinary skill in the art.

In a further embodiment, the present invention relates to host cells containing the above-described construct. The host cell can be a higher eukaryotic cell, such as a mammalian cell, or a lower eukaryotic cell, such as a yeast cell, or the host cell can be a prokaryotic cell, such as a bacterial cell.

10 Introduction of the construct into the host cell can be effected by calcium phosphate transfection, DEAE-Dextran mediated transfection, or electroporation (Davis, L., Dibner, M., Battey, I., *Basic Methods in Molecular Biology*, 1986)).

The constructs in host cells can be used in a conventional manner to produce the gene product encoded by the recombinant sequence. Alternatively, the polypeptides of the invention can be synthetically produced by conventional peptide synthesizers.

15

Proteins can be expressed in mammalian cells, yeast, bacteria, or other cells under the control of appropriate promoters. Cell-free translation systems can also be employed to produce such proteins using RNAs derived from the DNA constructs of the present invention. Appropriate cloning and expression vectors for use with prokaryotic and eukaryotic hosts are described by Sambrook.

20 *et al.*, *Molecular Cloning: A Laboratory Manual*, Second Edition, Cold Spring Harbor, N.Y., (1989), the disclosure of which is hereby incorporated by reference.

25

Transcription of a DNA encoding the polypeptides of the present invention by higher eukaryotes is increased by inserting an enhancer sequence into the vector. Enhancers are cis-acting elements of DNA, usually about from 10 to about 300 base pairs (bp), that act on a promoter to increase its transcription.

30 Examples include the SV40 enhancer on the late side of the replication origin (bp 100 to 270), a cytomegalovirus early promoter enhancer, a polyoma enhancer on the late side of the replication origin, and adenovirus enhancers.

Generally, recombinant expression vectors will include origins of replication and selectable markers permitting transformation of the host cell, e.g., the ampicillin resistance gene of *E. coli* and *S. cerevisiae* TRP1 gene, and a promoter derived from a highly-expressed gene to direct transcription of a downstream structural sequence. Such promoters can be derived from operons encoding glycolytic enzymes such as 3-phosphoglycerate kinase (PGK), α -factor, acid phosphatase, or heat shock proteins, among others. The heterologous structural sequence is assembled in appropriate phase with translation initiation and termination sequences, and preferably, a leader sequence capable of directing secretion of translated protein into the periplasmic space or extracellular medium. Optionally, the heterologous sequence can encode a fusion protein including an N-terminal identification peptide imparting desired characteristics, e.g., stabilization or simplified purification of expressed recombinant product.

Following transformation of a suitable host strain and growth of the host strain to an appropriate cell density, the selected promoter is derepressed by appropriate means (e.g., temperature shift or chemical induction) and cells are cultured for an additional period.

Cells are typically harvested by centrifugation, disrupted by physical or chemical means, and the resulting crude extract retained for further purification.

Microbial cells employed in expression of proteins can be disrupted by any convenient method, including freeze-thaw cycling, sonication, mechanical disruption, or use of cell lysing agents.

Various mammalian cell culture systems can also be employed to express recombinant protein. Examples of mammalian expression systems include the COS-7 lines of monkey kidney fibroblasts, described by Gluzman, *Cell*, 23:175 (1981), and other cell lines capable of expressing a compatible vector, for example, the C127, 3T3, CHO, HeLa and BHK cell lines. Mammalian expression vectors will comprise an origin of replication, a suitable promoter and enhancer, and also any necessary ribosome binding sites, polyadenylation site, splice donor and acceptor sites, transcriptional termination sequences, and 5' flanking nontranscribed sequences. DNA sequences derived from the SV40 viral

genome, for example, SV40 origin, early promoter, enhancer, splice, and polyadenylation sites can be used to provide the required nontranscribed genetic elements.

5 Polypeptides are recovered and purified from recombinant cell cultures by methods used heretofore, including ammonium sulfate or ethanol precipitation, acid extraction, anion or cation exchange chromatography, phosphocellulose chromatography, hydrophobic interaction chromatography, affinity chromatography, hydroxyapatite chromatography and lectin chromatography. It is preferred to have low concentrations (approximately 0.1-5
10 mM) of calcium ion present during purification (Price, *et al.*, *J. Biol. Chem.*, 244:917 (1969)). Protein refolding steps can be used, as necessary, in completing configuration of the mature protein. Finally, high performance liquid chromatography (HPLC) can be employed for final purification steps.

15 The polypeptides of the present invention can be a naturally purified product, or a product of chemical synthetic procedures, or produced by recombinant techniques from a prokaryotic or eukaryotic host (for example, by bacterial, yeast, higher plant, insect and mammalian cells in culture). Depending upon the host employed in a recombinant production procedure, the polypeptides of the present invention can be glycosylated with mammalian or other eukaryotic
20 carbohydrates or can be non-glycosylated.

The polypeptides of the present invention can be modified to improve stability and increase potency by means known in the art. For example, L-amino acids can be replaced by D-amino acids, the amino terminus can be acetylated, or the carboxyl terminus modified, e.g., ethylamine-capped (Dawson,
25 D.W., *et al.*, *Mol. Pharmacol.*, 55: 332-338 (1999)).

The polypeptide of the present invention can also be employed as gene therapy in accordance with the present invention by expression of such polypeptide *in vivo*.

30 Various viral vectors that can be utilized for gene therapy as taught herein include adenovirus, herpes virus, vaccinia, adeno-associated virus (AAV), or, preferably, an RNA virus such as a retrovirus. Preferably, the retroviral vector is a derivative of a murine or avian retrovirus, or is a lentiviral vector.

The preferred retroviral vector is a lentiviral vector. Examples of retroviral vectors in which a single foreign gene can be inserted include, but are not limited to: Moloney murine leukemia virus (MoMuLV), Harvey murine sarcoma virus (HaMuSV), murine mammary tumor virus (MuMTV), SIV, BIV, HIV and Rous Sarcoma Virus (RSV). A number of additional retroviral vectors can incorporate multiple genes. All of these vectors can transfer or incorporate a gene for a selectable marker so that transduced cells can be identified and generated. By inserting a zinc finger derived-DNA binding polypeptide sequence of interest into the viral vector, along with another gene that encodes the ligand for a receptor on a specific target cell, for example, the vector is made target specific. Retroviral vectors can be made target specific by inserting, for example, a polynucleotide encoding a protein. Preferred targeting is accomplished by using an antibody to target the retroviral vector. Those of skill in the art will know of, or can readily ascertain without undue experimentation, specific polynucleotide sequences which can be inserted into the retroviral genome to allow target specific delivery of the retroviral vector containing the zinc finger-nucleotide binding protein polynucleotide.

Since recombinant retroviruses are defective, they require assistance in order to produce infectious vector particles. This assistance can be provided, for example, by using helper cell lines that contain plasmids encoding all of the structural genes of the retrovirus under the control of regulatory sequences within the LTR. These plasmids are missing a nucleotide sequence which enables the packaging mechanism to recognize an RNA transcript for encapsitation. Helper cell lines which have deletions of the packaging signal include but are not limited to Ψ 2, PA317 and PA12, for example. These cell lines produce empty virions, since no genome is packaged. If a retroviral vector is introduced into such cells in which the packaging signal is intact, but the structural genes are replaced by other genes of interest, the vector can be packaged and vector virion produced. The vector virions produced by this method can then be used to infect a tissue cell line, such as NIH 3T3 cells, to produce large quantities of chimeric retroviral virions.

Another targeted delivery system for polynucleotides encoding zinc finger derived-DNA binding polypeptides is a colloidal dispersion system.

Colloidal dispersion systems include macromolecule complexes, nanocapsules, microspheres, beads, and lipid-based systems including oil-in-water emulsions, micelles, mixed micelles, and liposomes. The preferred colloidal system of this invention is a liposome. Liposomes are artificial membrane vesicles which are useful as delivery vehicles *in vitro* and *in vivo*. It has been shown that large unilamellar vesicles (LUV), which range in size from 0.2-4.0 μm can encapsulate a substantial percentage of an aqueous buffer containing large macromolecules.

RNA, DNA and intact virions can be encapsulated within the aqueous interior and be delivered to cells in a biologically active form (Fraley, *et al.*, *Trends Biochem. Sci.*, 6:77, (1981)). In addition to mammalian cells, liposomes have been used for delivery of polynucleotides in plant, yeast and bacterial cells. In order for a liposome to be an efficient gene transfer vehicle, the following characteristics should be present: (1) encapsulation of the genes of interest at high efficiency while not compromising their biological activity; (2) preferential and substantial binding to a target cell in comparison to non-target cells; (3) delivery of the aqueous contents of the vesicle to the target cell cytoplasm at high efficiency; and (4) accurate and effective expression of genetic information (Mannino, *et al.*, *Biotechniques*, 6:682, (1988)).

The composition of the liposome is usually a combination of phospholipids, particularly high-phase-transition-temperature phospholipids, usually in combination with steroids, especially cholesterol. Other phospholipids or other lipids can also be used. The physical characteristics of liposomes depend on pH, ionic strength, and the presence of divalent cations.

Examples of lipids useful in liposome production include phosphatidyl compounds, such as phosphatidylglycerol, phosphatidylcholine, phosphatidylserine, phosphatidylethanolamine, sphingolipids, cerebroside, and gangliosides. Particularly useful are diacylphosphatidylglycerols, where the lipid moiety contains from 14-18 carbon atoms, particularly from 16-18 carbon atoms, and is saturated. Illustrative phospholipids include egg phosphatidylcholine, dipalmitoylphosphatidylcholine and distearoylphosphatidylcholine.

The targeting of liposomes has been classified based on anatomical and mechanistic factors. Anatomical classification is based on the level of selectivity, for example, organ-specific, cell-specific, and organelle-specific. Mechanistic targeting can be distinguished based upon whether it is passive or active. Passive targeting utilizes the natural tendency of liposomes to distribute to cells of the reticulo-endothelial system (RES) in organs which contain sinusoidal capillaries. Active targeting, on the other hand, involves alteration of the liposome by coupling the liposome to a specific ligand such as a monoclonal antibody, sugar, glycolipid, or protein, or by changing the composition or size of the liposome in order to achieve targeting to organs and cell types other than the naturally occurring sites of localization.

The surface of the targeted delivery system can be modified in a variety of ways. In the case of a liposomal targeted delivery system, lipid groups can be incorporated into the lipid bilayer of the liposome in order to maintain the targeting ligand in stable association with the liposomal bilayer. Various linking groups can be used for joining the lipid chains to the targeting ligand.

In general, the compounds bound to the surface of the targeted delivery system will be ligands and receptors which will allow the targeted delivery system to find and "home in" on the desired cells. A ligand can be any compound of interest which will bind to another compound, such as a receptor.

In general, surface membrane proteins which bind to specific effector molecules are referred to as receptors. In the present invention, antibodies are preferred receptors. Antibodies can be used to target liposomes to specific cell-surface ligands. For example, certain antigens expressed specifically on tumor cells, referred to as tumor-associated antigens (TAAs), can be exploited for the purpose of targeting antibody-zinc finger-nucleotide binding protein-containing liposomes directly to the malignant tumor. Since the zinc finger-nucleotide binding protein gene product can be indiscriminate with respect to cell type in its action, a targeted delivery system offers a significant improvement over randomly injecting non-specific liposomes. A number of procedures can be used to covalently attach either polyclonal or monoclonal antibodies to a liposome bilayer. Antibody-targeted liposomes can include monoclonal or polyclonal

antibodies or fragments thereof such as Fab, or F(ab')₂, as long as they bind efficiently to an the antigenic epitope on the target cells. Liposomes can also be targeted to cells expressing receptors for hormones or other serum factors.

5 There are available to one skilled in the art multiple viral and non-viral methods suitable for introduction of a nucleic acid molecule into a target cell. Genetic manipulation of primary tumor cells is well known in the art. Genetic modification of a cell can be accomplished using one or more techniques well known in the gene therapy field (Mulligan, R.C. *Human Gene Therapy*, 5(4):543-563 (1993)). Viral transduction methods can comprise the use of a
10 recombinant DNA or an RNA virus comprising a nucleic acid sequence that drives or inhibits expression of a protein having sialyltransferase activity to infect a target cell. A suitable DNA virus for use in the present invention includes but is not limited to an adenovirus (Ad), adeno-associated virus (AAV), herpes virus, vaccinia virus or a polio virus. A suitable RNA virus for use in the present
15 invention includes but is not limited to a retrovirus or Sindbis virus. It is to be understood by those skilled in the art that several such DNA and RNA viruses exist that can be suitable for use in the present invention.

Adenoviral vectors are useful for gene transfer into eukaryotic cells, to study eukaryotic gene expression, for vaccine development, and in
20 animal models. Ad-mediated gene therapy has also been utilized in humans, such as for the transfer of the cystic fibrosis transmembrane conductance regulator (CFTR) gene to the lung. Routes for administering recombinant Ad to different tissues *in vivo* include, for example, intratracheal instillation, injection into muscle, peripheral intravenous injection and stereotactic inoculation to brain.
25 The adenoviral vector, then, is widely available to one skilled in the art and is suitable for use in the present invention.

Adeno-associated virus (AAV) has recently been introduced as a gene transfer system with potential applications in gene therapy. Wild-type AAV has been reported to demonstrate high-level infectivity, broad host range and
30 specificity in integrating into the host cell genome. Herpes simplex virus type-1 (HSV-1) is attractive as a vector system, especially for use in the nervous system because of its neurotropic property. Vaccinia virus, of the poxvirus family, has

also been developed as an expression vector. Each of the above-described vectors are widely available to one skilled in the art and would be suitable for use in the present invention.

5 Retroviral vectors are capable of infecting a large percentage of the target cells and integrating into the cell genome. Retroviruses were developed as gene transfer vectors relatively earlier than other viruses, and were first used successfully for gene marking and transducing the cDNA of adenosine deaminase (ADA) into human lymphocytes. Preferred retroviruses include lentiviruses. In preferred embodiments, the retrovirus is selected from the group consisting of
10 HIV, BIV and SIV.

"Non-viral" delivery techniques that have been used or proposed for gene therapy include DNA-ligand complexes, adenovirus-ligand-DNA complexes, direct injection of DNA, CaPO_4 precipitation, gene gun techniques, electroporation, liposomes and lipofection. Any of these methods are widely
15 available to one skilled in the art and would be suitable for use in the present invention. Other suitable methods are available to one skilled in the art, and it is to be understood that the present invention can be accomplished using any of the available methods of transfection. Several such methodologies have been utilized by those skilled in the art with varying success. Lipofection can be accomplished
20 by encapsulating an isolated DNA molecule within a liposomal particle and contacting the liposomal particle with the cell membrane of the target cell. Liposomes are self-assembling, colloidal particles in which a lipid bilayer, composed of amphiphilic molecules such as phosphatidyl serine or phosphatidyl choline, encapsulates a portion of the surrounding media such that the lipid
25 bilayer surrounds a hydrophilic interior. Unilammellar or multilammellar liposomes can be constructed such that the interior contains a desired chemical, drug, or, as in the instant invention, an isolated DNA molecule.

The cells can be transfected *in vivo*, *ex vivo*, or *in vitro*. The cells can be transfected as primary cells isolated from a patient or a cell line derived
30 from primary cells, and are not necessarily autologous to the patient to whom the cells are ultimately administered. Following *ex vivo* or *in vitro* transfection, the cells can be implanted into a host.

In order to obtain transcription of the nucleic acid of the present invention within a target cell, a transcriptional regulatory region capable of driving gene expression in the target cell is utilized. The transcriptional regulatory region can comprise a promoter, enhancer, silencer or repressor element and is functionally associated with a nucleic acid of the present invention. Preferably, the transcriptional regulatory region drives high level gene expression in the target cell. Transcriptional regulatory regions suitable for use in the present invention include but are not limited to the human cytomegalovirus (CMV) immediate-early enhancer/promoter, the SV40 early enhancer/promoter, the JC polyomavirus promoter, the albumin promoter, PGK and the α -actin promoter coupled to the CMV enhancer.

The vectors of the present invention can be constructed using standard recombinant techniques widely available to one skilled in the art. Such techniques can be found in common molecular biology references such as Sambrook, et al., *Molecular Cloning: A Laboratory Manual*, Cold Spring Harbor Laboratory Press (1989), D. Goeddel, ed., *Gene Expression Technology, Methods in Enzymology* series, Vol. 185, Academic Press, San Diego, CA (1991), and Innis, et al. *PCR Protocols: A Guide to Methods and Applications* Academic Press, San Diego, CA (1990).

Administration of a polypeptide or a nucleic acid of the present invention to a target cell *in vivo* can be accomplished using any of a variety of techniques well known to those skilled in the art.

The vectors of the present invention can be administered orally, parentally, by inhalation spray, rectally, or topically in dosage unit formulations containing conventional pharmaceutically acceptable carriers, adjuvants, and vehicles. The term parenteral as used herein includes, subcutaneous, intravenous, intramuscular, intrasternal, infusion techniques or intraperitoneally. Suppositories for rectal administration of the drug can be prepared by mixing the drug with a suitable non-irritating excipient such as cocoa butter and polyethylene glycols that are solid at ordinary temperatures but liquid at the rectal temperature and will therefore melt in the rectum and release the drug.

The dosage regimen for treating a disorder or a disease with the vectors of this invention and/or compositions of this invention is based on a variety of factors, including the type of disease, the age, weight, sex, medical condition of the patient, the severity of the condition, the route of administration, and the particular compound employed. Thus, the dosage regimen can vary widely, but can be determined routinely using standard methods.

The pharmaceutically active compounds of this invention can be processed in accordance with conventional methods of pharmacy to produce medicinal compositions or agents for administration to patients, including humans and other mammals. For oral administration, the pharmaceutical composition can be in the form of, for example, a liquid, an ocular insert, a capsule, a tablet, a suspension. The pharmaceutical composition is preferably made in the form of a dosage unit containing a given amount of active agent. For example, these can contain an amount of vector from about 10^3 - 10^{15} viral particles, preferably from about 10^6 - 10^{12} viral particles. A suitable daily dose for a human or other mammal can vary widely depending on the condition of the patient and other factors, but, once again, can be determined using routine methods. Administration can be by injection of the active agent as a composition together with suitable pharmacologically acceptable carriers such as saline, dextrose, or water.

While the nucleic acids and /or vectors of the invention can be administered as the sole active pharmaceutical agent, they can also be used in combination with one or more vectors of the invention or other agents. When administered as a combination, the therapeutic agents can be formulated as separate compositions that are given at the same time or different times, or the therapeutic agents can be given as a single composition.

The polypeptide of the present invention can also be utilized in combination with a suitable pharmaceutical carrier. Such compositions comprise a therapeutically effective amount of the protein, and a pharmaceutically acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration.

The invention also provides a pharmaceutical pack or kit comprising one or more containers filled with one or more of the ingredients of the pharmaceutical compositions of the invention. Associated with such container(s) can be a notice in the form prescribed by a governmental agency
5 regulating the manufacture, use or sale of pharmaceuticals or biological products, which notice reflects approval by the agency of manufacture, use or sale for human administration. In addition, the polypeptide of the present invention can be employed on conjunction with other therapeutic compounds.

The pharmaceutical compositions can be administered in a
10 convenient manner, such as the intraocular, eye drop, and systemic routes. The amounts and dosage regimens of the tRNA synthetase derived polypeptides administered to a patient will depend on a number of factors, such as the mode of administration, the nature of the condition being treated, the body weight of the subject being treated and the judgment of the prescribing physician. Generally
15 speaking, the polypeptide is administered in therapeutically effective doses of at least about 10 µg/kg body weight. Preferably, the dosage is about 10 µg/kg body weight to about 1 mg/kg body weight daily, taking into the account the frequency, routes of administration, symptoms, etc.

Angiostatic trpRS therapy can be used to oppose the angiogenic
20 activity of endogenous and exogenous angiogenic factors, and to prevent the further growth or even regress solid tumors, since angiogenesis and neovascularization are essential steps in solid tumor growth. Such therapies can also be used to treat rheumatoid arthritis, psoriasis and diabetic retinopathy which are all characterized by abnormal angiogenesis.

25 Compositions are provided containing therapeutically effective amounts and concentrations of recombinant adenovirus delivery vectors for delivery of therapeutic gene products to cells that express a particular receptor. These cells include cells of the eye. Of particular interest are photoreceptor cells of the eye. Administration can be effected by any means through which
30 contacting with the photoreceptors is effected. To provide access to photoreceptor cells, preferable modes of administration include, but are not limited to, subretinal injection or intravitreal injection.

The recombinant viral compositions can also be formulated for implantation into the anterior or posterior chamber of the eye, preferably the vitreous cavity, in sustained released formulations, such as adsorbed to biodegradable supports, including collagen sponges, or in liposomes. Sustained release formulations can be formulated for multiple dosage administration, so that during a selected period of time, such as a month or up to about a year, several dosages are administered. Thus, for example, liposomes can be prepared such that a total of about two to up to about five or more times the single dosage is administered in one injection.

The vectors are formulated in an ophthalmologically acceptable carrier for intraocular, preferably intravitreal, administration in a volume of between about 0.05 ml and 0.15 ml, preferably about 0.05 and 0.1 ml.

The compositions can be provided in a sealed sterile vial containing an amount of the active agent that upon intraocular administration delivers a sufficient amount of viral particles to the photoreceptors in a volume of about 50 to 150 μ l, containing at least about 10^7 , more preferably at least about 10^8 plaque forming units in such volume. Typically, the vials will, thus, contain about 0.15 ml of the composition.

To prepare such compositions, the viral particles are dialyzed into a suitable ophthalmologically acceptable carrier or viral particles can be concentration and/or mixed therewith. The resulting mixture can be a solution, suspension or emulsion. In addition, the viral particles can be formulated as the sole pharmaceutically active ingredient in the composition or can be combined with other active agents for the particular disorder treated.

For administration by intraocular injection or via eye drops, suitable carriers include, but are not limited to, physiological saline, phosphate buffered saline (PBS), balanced salt solution (BSS), Ringers lactate solution, and solutions containing thickening and solubilizing agents, such as glucose, polyethylene glycol, and polypropylene glycol and mixtures thereof. Liposomal suspensions can also be suitable as pharmaceutically acceptable carriers. These can be prepared according to methods known to those skilled in the art. Suitable ophthalmologically acceptable carriers are known. Solutions or mixtures

intended for ophthalmic use can be formulated as 0.01% - 10% isotonic solutions, pH about 5-7, with appropriate salts (see, *e.g.*, U.S. Patent No. 5,116,868, which describes typical compositions of ophthalmic irrigation solutions and solutions for local application). Such solutions, which have a pH
5 adjusted to about 7.4, contain, for example, 90-100 mM sodium chloride, 4-6 mM dibasic potassium phosphate, 4-6 mM dibasic sodium phosphate, 8-12 mM sodium citrate, 0.5-1.5 mM magnesium chloride, 1.5-2.5 mM calcium chloride, 15-25 mM sodium acetate, 10-20 mM sodium D,L- β -hydroxybutyrate and 5-5.5 mM glucose.

10 The compositions can be prepared with carriers that protect the active agent against rapid elimination from the body, such as time release formulations or coatings. Such carriers include controlled release formulations, such as, but not limited to, microencapsulated delivery systems, and biodegradable, biocompatible polymers, such as ethylene vinyl acetate,
15 polyanhydrides, polyglycolic acid, polyorthoesters, polylactic acid and other types of implants that can be placed directly into the anterior or posterior chamber or vitreous cavity of the eye. The compositions can also be administered in pellets, such as ELVAX® pellets (ethylene-vinyl acetate copolymer resin, DuPont).

20 Liposomal suspensions, including tissue-targeted liposomes, can also be suitable as pharmaceutically acceptable carriers. For example, liposome formulations can be prepared by methods known to those of skill in the art (see, *e.g.*, Kimm *et al. Bioch. Bioph. Acta* 728:339-398 (1983); Assil *et al. Arch Ophthalmol.* 105:400 (1987); and U.S. Patent No. 4,522,811). The viral
25 particles can be encapsulated into the aqueous phase of liposome systems.

The active materials or agents can also be mixed with other active materials, that do not impair the desired action, or with materials that supplement the desired action or have other action, including viscoelastic materials, such as hyaluronic acid, which is sold under the trademark HEALON® (Pharmacia, Inc),
30 which is a solution of a high molecular weight (MW) of about 3 millions fraction of sodium hyaluronate (see, *e.g.*, U.S. Patent Nos. 5,292,362, 5,282,851, 5,273,056, 5,229,127, 4,517,295 and 4,328,803), and a resins sold under the

trademark VISCOAT® (available from Alcon Surgical, Inc.), which are
fluorine-containing (meth)acrylates, such as,
1H,1H,2H,2H-heptadecafluorodecylmethacrylate (see, *e.g.*, U.S. Patent Nos.
5,278,126, 5,273,751 and 5,214,080; and resins sold under the trademark
5 ORCOLON® (Optical Radiation Corporation, see *e.g.*, U.S. Patent No.
5,273,056), and methylcelluloses, methyl hyaluronates, polyacrylamides and
polymethacrylamides (see *e.g.*, U.S. Patent No.5,273,751). The viscoelastic
materials are present generally in amounts ranging from about 0.5 to 5.0%,
preferably 1 to 3 % by weight of the conjugate material and serve to coat and
10 protect the treated tissues. The compositions can also include a dye, such as
methylene blue or other inert dye, so that the composition can be seen when
injected into the eye. Additional active agents can be included.

The compositions can be enclosed in ampules, disposable syringes
or multiple or single dose vials made of glass, plastic or other suitable material.
15 Such enclosed compositions can be provided in kits. In particular, kits containing
vials, ampules or other container, preferably disposable vials with sufficient
amount of the composition to deliver about 0.100 ml thereof, and disposable
needles, preferably self sealing 25-33 gauge needles, or smaller, are provided
herein.

20 Finally, the compositions can be packaged as articles of
manufacture containing packaging material, typically a vial, an
ophthalmologically acceptable composition containing a polypeptide of the
present invention and a label that indicates the therapeutic use of the composition.

Also provided are kits for practice of the methods herein. The kits
25 contain one or more containers, such as sealed vials, with sufficient composition
for single dosage administration, and one or more needles, such as self sealing
25-33 gauge or smaller needles, preferably 33 gauge or smaller needles, with
precisely calibrated syringes or other precisely calibrated delivery device, suitable
for intravitreal injection.

30 Administration of the composition is preferably by intraocular
injection, although other modes of administration can be effective, if the
sufficient amount of the compound achieves contact with the vitreous cavity.

Intraocular injection can be effected by intravitreal injection, aqueous humor injection or injection into the external layers of the eye, such as subconjunctival injection or subtenon injection, or by topical application to the cornea, if a penetrating formulation is used.

5 For any particular patient, specific dosage regimens should be adjusted over time according to the individual need and the professional judgment of the person administering or supervising the administration of the recombinant viruses. The concentration and amount ranges set forth herein are exemplary only and are not intended to limit the scope or practice of the claimed methods

10 The Examples that follow are illustrative of specific embodiments of the invention, and of various uses thereof. They are provided for illustrative and explanatory purposes only, but are not to be taken as limiting.

EXAMPLE 1. Preparation of Endotoxin-Free Recombinant TrpRS

Endotoxin-free recombinant human TrpRS was prepared as follows.
15 Plasmids encoding full-length TrpRS (amino acid residues 1-471 of SEQ ID NO:1), or truncated TrpRS, hereinafter referred to as T2 (SEQ ID NO:12), consisting essentially of residues 94-471 of SEQ ID NO:1 (i.e., residues 94-471 of full-length TrpRS) and a second truncated TrpRS, hereinafter referred to as T1 (SEQ ID NO:13), consisting essentially of residues 71-471 of SEQ ID NO:1 were prepared.
20 Each plasmid also encoded a C-terminal tag comprising six histidine residues (e.g. amino acid residues 472-484 of SEQ ID NO: 1), and an initial methionine residue. The His₆-tagged T1 has the amino acid sequence of SEQ ID NO:5, whereas the His₆-tagged T2 has the amino acid sequence of SEQ ID NO:7.

The above plasmids were introduced into *E. coli* strain BL 21 (DE 3)
25 (Novagen, Madison, WI). Human mature EMAPII, also encoding a C-terminal tag of six histidine residues, was similarly prepared for use. Overexpression of recombinant TrpRS was induced by treating the cells with isopropyl β -D-thiogalactopyranoside for 4 hours. Cells were then lysed and the proteins from the supernatant purified on HIS•BIND® nickel affinity columns (Novagen) according to
30 the manufacturer's suggested protocol. Following purification, TrpRS proteins were incubated with phosphate-buffered saline (PBS) containing 1 μ M ZnSO₄ and then free Zn²⁺ was removed (Kisselev *et al.*, *Eur. J. Biochem.* 120:511-17 (1981)).

Endotoxin was removed from protein samples by phase separation using Triton X-114 (Liu *et al.*, *Clin. Biochem.* 30:455-63 (1997)). Protein samples were determined to contain less than 0.01 units of endotoxin per mL using an E-TOXATE® gel-clot assay (Sigma, St. Louis, MO). Protein concentration was determined by the Bradford assay (Bio-Rad, Hercules, CA) using bovine serum albumin (BSA) as a standard.

EXAMPLE 2. Cleavage of Human TrpRS by PMN Elastase

Cleavage of human full-length TrpRS by PMN elastase was examined. TrpRS was treated with PMN elastase in PBS (pH 7.4) at a protease:protein ratio of 1:3000 for 0, 15, 30, or 60 minutes. Following cleavage, samples were analyzed on 12.5% SDS-polyacrylamide gels. PMN elastase cleavage of a full-length TrpRS of about 53 kDa, encoded by nucleotides 3428 to 4738 of DNA SEQ ID NO:2) generated a major fragment of about 46 kDa (SEQ ID NO:5, T1 having the C-terminal histidine tag) and a minor fragment of about 43 kDa (SEQ ID NO:7, T2 having the C-terminal histidine tag).

Western blot analysis with antibodies directed against the carboxyl-terminal His₆-tag of the recombinant TrpRS protein revealed that both fragments possessed the His₆-tag at their carboxyl-terminus. Thus, only the amino-terminus of two TrpRS fragments has been truncated. The amino-terminal sequences of the TrpRS fragments were determined by Edman degradation using an ABI Model 494 sequencer. Sequencing of these fragments showed that the amino-terminal sequences were S-N-H-G-P (SEQ ID NO:8) and S-A-K-G-I (SEQ ID NO:9), indicating that the amino-terminal residues of the major and minor TrpRS fragments were located at positions 71 and 94, respectively, of full-length TrpRS. These human TrpRS constructs are summarized in FIGURE 1. Signature sequences -HVGH- (SEQ ID NO:10) and -KMSAS- (SEQ ID NO:11) are shown in boxes.

The angiostatic activity of the major and minor TrpRS fragments was analyzed in angiogenesis assays. Recombinant forms of the major and minor TrpRS fragments SEQ ID NO:5 and SEQ ID NO:7 each having a C-terminal histidine tag (amino acid residues 472-484 of SEQ ID NO:1) were used in these assays. Both TrpRS fragments were capable of inhibiting angiogenesis.

EXAMPLE 3. Truncated Fragments of Trp-RS Show Potent

Angiostatic Effect for Retinal Angiogenesis

Angiostatic activity of truncated forms derived from tryptophanyl-rRNA synthetase (TrpRS, 53 kd; SEQ ID NO:1) was examined, in a post-natal mouse retinal angiogenesis model Friedlander *et al.* Abstracts 709-B84 and 714-B89, *IOVS* 41(4):138-139 (March 15, 2000) has reported that postnatal retinal angiogenesis proceeds in stages in the mouse. The present invention provides a method of assaying angiogenesis inhibition by exploiting this staged retinal vascularization.

Endotoxin-free recombinant mini-TrpRS (48 kDa splice variant of histidine tagged TrpRS; SEQ ID NO:3) and T2 (43 kDa cleavage product of histidine tagged TrpRS; SEQ ID NO:7) were prepared as recombinant proteins. These proteins were injected intra-vitreally into neonatal Balb/C mice on postnatal (P) day 7 or 8 and the retinas harvested on P12 or P13. Collagen IV antibody and fluorescein-conjugated secondary antibody were used to visualize the vessels in retinal whole mount preparations. Anti-angiogenic activity was evaluated by confocal microscopic examination based upon the effect of injected proteins on formation of the deep, outer, vascular plexus. Intra-vitreous injection and retina isolation was performed with a dissecting microscope (SMZ 645, Nikon, Japan). An eyelid fissure was created in postnatal day 7 (P7) mice with a fine blade to expose the globe for injection of T2 (5 pmol) or TrpRS (5 pmol). The samples (0.5 μ l) were injected with a syringe fitted with a 32-gauge needle (Hamilton Company, Reno, NV). The injection was made between the equator and the corneal limbus; during injection the location of the needle tip was monitored by direct visualization to determine that it was in the vitreal cavity. Eyes with needle-induced lens or retinal damage were excluded from the study. After the injection, the eyelids were repositioned to close the fissure.

On postnatal day 12 (P12), animals were euthanized and eyes enucleated. After 10 minutes in 4% paraformaldehyde (PFA) the cornea, lens, sclera, and vitreous were excised through a limbal incision. The isolated retina was prepared for staining by soaking in methanol for 10 minutes on ice, followed by blocking in 50% fetal bovine serum (Gibco, Grand Island, NY) with 20%

normal goat serum (The Jackson Laboratory, Bar Harbor, ME) in PBS for 1 hour on ice. The blood vessels were specifically visualized by staining the retina with a rabbit anti-mouse collagen IV antibody (Chemicon, Temecula, CA) diluted 1:200 in blocking buffer for 18 h at 4 °C. An ALEXA FLUOR®
5 594-conjugated goat anti-rabbit IgG antibody (Molecular Probes, Eugene, OR) (1:200 dilution in blocking buffer) was incubated with the retina for 2 h at 4 °C. The retinas were mounted with slow-fade mounting media M (Molecular Probes, Eugene, OR).

Angiostatic activity was evaluated based upon the degree of
10 angiogenesis in the deep, outer retinal vascular layer (secondary layer) that forms between P8 and P12. The appearance of the inner blood vessel network (primary layer) was evaluated for normal development and signs of toxicity. None of the protein constructs used in this example produced any adverse effects on the primary layer.

FIG. 2 provides a photomicrographic depiction of the ability of T2
15 to inhibit vascularization of the secondary deep network of the mouse retina. In FIG. 2, row A shows the vascular network of a retina exposed to TrpRS, Row B shows the vascular network of a retina exposed to Mini-TrpRS, and row C shows the vascular network of a retina exposed to polypeptide T2 of the present
20 invention. The first (left) column shows the primary superficial network, and the second column shows the secondary deep network. As is evident from FIG. 2, none of the polypeptides affected the primary superficial network, whereas only T2 significantly inhibited vascularization of the secondary deep network.

Most PBS-treated eyes exhibited normal retinal vascular
25 development, but complete inhibition of the outer vascular layer was observed in about 8.2% (n=73) of the treated eyes. Complete inhibition of the outer network was observed in 28% of mini-TrpRS (0.5 mg/ml)-treated eyes (n=75). The smaller, truncated form (T2) was a far more potent inhibitor of angiogenesis in a dose dependent fashion; 14.3% were completely inhibited after treatment with
30 0.1 mg/ml of T2 (n=14), 40% after treatment with 0.25 mg/ml (n=20) and 69.8% inhibited completely after 0.5 mg/ml (n=53). The data for the 0.5 mg/ml treatments are presented graphically in FIG. 3. Extracts of mouse retina

contain a protein with the same apparent molecular mass and immunoreactivity as human mini-TrpRS, as analyzed by SDS-PAGE and Western Blot. Full-length mouse and human TrpRS share about 88% amino acid identity and contain 475 and 471 amino acids, respectively. Truncated forms of TrpRS, especially T2, have a potent angiostatic effect on retinal vascular development.

EXAMPLE 4. Matrigel Angiogenesis Assay.

A mouse matrigel angiogenesis assay was used to examine the angiostatic activity of T2 (SEQ ID NO: 7) according to the methods described by Brooks *et al. Methods Mol. Biol.*, 129: 257-269 (1999) and Eliceiri *et al. Mol. Cell*, 4: 915-924 (1999). It was performed as described with the following modifications. Athymic wehi mice were subcutaneously implanted with 400 μ l growth-factor depleted matrigel (Becton Dickinson, Franklin Lakes, NJ) containing 20 nM VEGF. The angiostatic activity of T2 was initially tested by including 2.5 μ M T2 in the matrigel plug. The potency was determined by including various concentrations of T2 in the plug. On day 5, the mice were intravenously injected with the fluorescein-labeled endothelial binding lectin Griffonia (Bandeiraea) Simplicifolia I, isolectin B4 (Vector Laboratories, Burlingame, CA) and the matrigel plugs were resected. The fluorescein content of each plug was quantified by spectrophotometric analysis after grinding the plug in RIPA buffer (10 mM sodium phosphate, pH 7.4, 150 mM sodium chloride, 1% Nonidet P-40, 0.5% sodium deoxycholate, 0.1% sodium dodecyl sulfate).

EXAMPLE 5. Localization of T2 Binding within the Retina.

To assess the uptake and localization of T2 injected into the retina, fluorescein-labeled (ALEXA[®] 488, Molecular Probes, Inc., Eugene OR) T2 was injected into the vitreous of the eye on postnatal day 7 (P7). Globes were harvested on P8 and P12 and fixed in 4% PFA for 15 min. The retinas were further dissected free of adherent nonretinal tissue and placed in 4% PFA overnight at 4 °C and then embedded in medium (TISSUE-TEK[®] O.C.T., Sakura FineTechnical Co., Japan) on dry ice. Cryostat sections (10 micron) were rehydrated with PBS and blocked with 5% BSA, 2% normal goat serum in PBS.

Blood vessels were visualized with anti-mouse collagen IV antibody as described above. VECTASHIELD® containing DAPI nuclear stain (Vector Laboratories, Burlingame, CA) was used to mount the tissues with a cover slip.

Alternatively, unstained retina sections were incubated with 200 nM fluorescein-labeled full-length TrpRS or fluorescein-labeled T2 in blocking buffer overnight at 4 °C. Sections were washed six times for 5 minutes each in PBS, followed by incubation with 1 µg/ml DAPI for 5 minutes for visualization of the nuclei. Pre-blocking with unlabeled T2 was performed by incubating 1 µM unlabeled T2 for 8 hours at 4 °C prior to incubation with fluorescein-labeled T2. Retinas were examined with a multiphoton BioRad MRC1024 confocal microscope. 3-D vascular images were produced from a set of Z-series images using the Confocal Assistant software (BioRad, Hercules, CA).

Angiostatic Potency of T2 in the Mouse Matrigel Plug Assay. We examined T2 (SEQ ID NO: 7) to determine whether it had angiostatic activity, even though it had lost aminoacylation activity. The mouse matrigel assay was used to examine the angiostatic activity of T2 *in vivo*. VEGF₁₆₅-induces the development of blood vessels into the mouse matrigel plug. When T2 was added to the matrigel along with VEGF₁₆₅, angiogenesis was blocked in a dose-dependent manner with a IC₅₀ of 1.7 nM as shown in FIG. 4.

Fluorescein-labeled T2 Localizes to Retinal Blood Vessels. In order to visualize the intraocular localization of T2 (SEQ ID NO: 7), we examined the distribution of fluorescein-labeled T2 following intravitreal injection on postnatal day 7. Retinas were isolated the following day, sectioned and examined using confocal microscopy. The distribution of the injected protein was restricted to blood vessels. This localization was confirmed by co-staining labeled T2 treated eyes with an fluorescein-labeled (ALEXA® 594) anti-collagen IV antibody (data not shown). Five days after injection of fluorescein-labeled T2 (on P12), the green fluorescence of the labeled T2 was still visible (FIG. 5A). In these retinas, no secondary vascular layer was observed at P12, indicating that the fluorescein-labeled T2 retained angiostatic activity comparable to unlabeled T2. Retinas injected on P7 with fluorescein-labeled full-length TrpRS developed a secondary vascular layer by P12 but no vascular staining was observed (FIG.

5B). In FIG. 5, fluorescein-labeled proteins are green, collagen-labeled vessels are red, and nuclei are blue.

To further evaluate the binding properties of labeled T2, cross-sectioned slices of normal neonatal retinas were stained with fluorescein-labeled T2. Under these conditions, fluorescein-labeled T2 only bound to blood vessels (FIG. 5C). The binding was specific as it was blocked by pre-incubation with unlabeled T2 (data not shown). No retinal vessel staining was observed when fluorescein-labeled full-length TrpRS was applied to the retinas (FIG. 5D), consistent with the absence of angiostatic activity of the full-length enzyme.

As shown in FIG. 5, fluorescein-labeled T2 is angiostatic and localizes to retinal blood vessels. Fluorescein-labeled T2 (FIG. 5A) or full-length TrpRS (FIG. 5B) were injected (0.5 μ l, intravitreal) on postnatal day 7 (P7). The retinas were harvested on P8 and stained with an anti-collagen IV antibody and DAPI nuclear stain. Labeled T2 (upper arrow pointing to vessel in FIG. 5A) localized to blood vessels in the primary superficial network (1°). Note that the secondary deep network is completely absent (2°). While both the primary (1°) and secondary (2°) vascular layers are present in eyes injected with fluorescein-labeled full-length TrpRS (arrows in FIG. 5B), no labeling is observed.

In a separate set of experiments, frozen sections of P15 retinas were stained with fluorescein-labeled T2 (FIG. 5C) or fluorescein-labeled full-length TrpRS (FIG. 5D) and imaged in the confocal scanning laser microscope. Labeled T2 selectively localized to blood vessels and appears as a bright green vessel penetrating the primary and secondary retinal vascular layers just below the label "2°" in FIG. 5C. No staining was observed with full-length TrpRS (FIG. 5D).

Full-length TrpRS contains a unique NH₂-terminal domain and lacks angiostatic activity. Removing part or all of this entire domain reveals a protein with angiostatic activity. The structures responsible for angiostatic activity of T2 appear to be contained within the core Rossmann fold nucleotide binding domain. The NH₂-terminal domain, which can be deleted by alternative splicing or by proteolysis, may regulate the angiostatic activity of TrpRS,

possibly by revealing a binding site necessary for angiostasis that is inaccessible in full-length TrpRS.

VEGF-induced angiogenesis in the mouse matrigel model was completely inhibited by T2 as was physiological angiogenesis in the neonatal retina. Interestingly, the most potent anti-angiogenic effect of TrpRS fragments *in vitro* and in CAM and matrigel models is observed in VEGF-stimulated angiogenesis. The neonatal mouse retinal angiogenesis results are consistent with a link between VEGF-stimulated angiogenesis and the angiostatic effects of TrpRS fragments; retinal angiogenesis in this system may be driven by VEGF. In addition, the inhibition observed in the retinal model was specific for newly developing vessels; pre-existing (at the time of injection) primary vascular layer vessels were unaltered by the treatment. While the mechanism for the angiostatic activity of T2 is not known, the specific localization of T2 to the retinal endothelial vasculature and the selective effect of T2 on newly developing blood vessels suggest that T2 may function through an endothelial cell receptor expressed on proliferating or migrating cells. Further understanding of the mechanism of T2 angiostatic activity requires identification of the relevant cell receptor.

A variety of cell types that produce, upon interferon- γ stimulation, the angiostatic mini TrpRS also produce angiostatic factors such as IP-10. Thus, these results raise the possibility of a role for TrpRS in normal, physiologically relevant pathways of angiogenesis. Another ubiquitous cellular protein— pro-EMAPII (p43)— has two apparently unrelated roles similar to those reported here for TrpRS. Pro-EMAPII assists protein translation by associating with the multisynthetase complex of mammalian aminoacyl tRNA synthetases. It is processed and secreted as EMAPII, and a role for EMAPII as an angiostatic mediator during lung development has been suggested.

Thus, T2 can be utilized in physiologically relevant angiogenic remodeling observed under normal or pathological conditions. In normal angiogenesis, T2 can aid in establishing physiologically important avascular zones present in some organs such as the foveal avascular zone of the central

retina. Pathological angiogenesis can occur if the cleavage of full-length TrpRS was inhibited, leading to an overgrowth of vessels.

In ocular diseases, neovascularization can lead to catastrophic loss of vision. These patients can potentially receive great benefit from therapeutic inhibition of angiogenesis. Vascular endothelial growth factor has been associated with neovascularization and macular edema in the retina, although it is believed that other angiogenic stimuli also have roles in retinal angiogenesis. We have observed an association between VEGF-stimulated angiogenesis and potent angiostatic activity of TrpRS fragments, making these molecules useful in the treatment of hypoxic, and other, proliferative retinopathies. There has been no report in the literature of an anti-angiogenic agent that completely inhibits angiogenesis 70% of the time, as does the T2 of the present invention (FIG. 5). Another advantage of TrpRS fragments is that they represent naturally occurring and, therefore, potentially non-immunogenic, anti-angiogenics. Thus, these molecules can be delivered via targeted cell- or viral vector-based therapy. Because many patients with neovascular eye diseases have associated systemic ischemic disease, local anti-angiogenic treatment with genetically engineered cells or viral vectors placed directly into the eye is desirable.

In addition to treatment of angiogenic retinopathies, the TrpRS fragments of the present invention, particularly T2 and angiogenesis inhibiting fragments thereof, can also inhibit solid tumor growth by preventing vascularization of the tumor. The TrpRS fragments of the present invention block VEGF-induced proliferation and chemotaxis of endothelial cells *in vitro*, and are thus useful in the treatment of any pathology involving unwanted endothelial cell proliferation and vascularization.
